Abstract. Background/Aim: Surgical treatment of renal cell carcinoma (RCC) with inferior vena cava (IVC) thrombus is associated with high morbidity and mortality rates, therefore presurgical systemic therapies are required in order to improve the safety and feasibility of the surgical procedure by decreasing the thrombus level and burden. The efficacy of presurgical combination therapy of immune checkpoint inhibitors (ICI) and tyrosine kinase inhibitors (TKI) for advanced renal cell carcinoma with IVC thrombus remains unclear. Case Report: We report a case of a 69-year-old male with cT3bN0M0 locally advanced RCC. We successfully performed a less invasive nephrectomy with thrombectomy, because nivolumab plus cabozantinib administration remarkably reduced the primary tumor and IVC thrombus, resulting in complete pathological response, as assessed with perioperative immunohistochemistry. Conclusion: To the best of our knowledge, this is the first report showing that nephrectomy could be safely performed for RCC with IVC thrombus after presurgical nivolumab plus cabozantinib therapy, leading to pathological complete response.

Surgical treatment of advanced renal cell carcinoma (RCC) with tumor thrombus extending into the inferior vena cava (IVC) requires careful management due to the high risk of operation-related deaths (1). Presurgical therapy, using tyrosine kinase inhibitors (TKI) or immune checkpoint inhibitors (ICI), for RCC with tumor thrombus is expected to shrink the tumor size and reduce surgical risks (2, 3). Currently, ICI-based therapy has been the standard first-line treatment for unresectable or metastatic RCC (4). In a recent study, Yoshida, et al. reported the efficacy of ICI-based therapy in the patients with RCC and IVC tumor thrombus in terms of primary tumor shrinkage and decrease of the tumor thrombus extent, resulting in reduced surgical risk (5). Herein, we report a case of RCC with IVC thrombus treated with nivolumab plus cabozantinib as presurgical therapy and subsequent safe nephrectomy, resulting in a pathological complete response (pCR). To the best of our knowledge, this is the first case in which a combination of nivolumab and cabozantinib as presurgical therapy resulted in shrinkage of the renal tumor and thrombus while achieving pCR.

Case Report

A 69-year-old male was referred to our Hospital (Iwate Medical University Hospital) for surgical treatment of a left renal tumor without any symptoms. He had a medical history of hypertension and diabetes mellitus. Abdominal enhanced computed tomography (CT) revealed a 30-mm left renal tumor (cT3bN0M0) with low-density enhancement (Figure 1A). We initially planned a robot-assisted partial nephrectomy, but the tumor grew rapidly during the 3-month waiting period, as per the patient’s preference. Follow-up CT revealed an expanding left renal tumor with a tumor thrombus in the left renal vein and IVC (Figure 1B). The International metastatic RCC Database Consortium (IMDC) prognostic risk scores were favorable. The clinical diagnosis
was cT3bN0M0 advanced RCC. We first performed CT-guided biopsy of the primary tumor. Pathological findings revealed RCC without sarcomatoid differentiation. However, biopsy specimens could not confirm the histological subtype diagnosis, including clear or non-clear cell carcinoma. Immunohistochemistry findings were positive for PAX8, CD10, AMACR, and E-cadherin and were negative for CK7. These results were not typical of renal clear cell carcinoma and diagnosis by needle biopsy did not lead to histological subtyping. We provided systemic therapy instead of immediate surgery because the tumor growth progressed rapidly, and we aimed to reduce the size of the primary tumor and thrombus. Therefore, we administered nivolumab 240 mg every 2 weeks and cabozantinib 40 mg once daily. The patient’s medical course was uneventful without drug withdrawal or dose reduction because of adverse events.

After 10 courses of nivolumab, CT revealed primary tumor and thrombus shrinkage (Figure 2). IVC thrombus level was downstaged from level II to I according to the Neves and Zincke’s classification system (6). We then planned curative surgery because the tumor had shrunk sufficiently for a safer surgery. We withdrew cabozantinib for one month and placed a temporary IVC filter immediately before surgery. Thereafter, we performed an open left nephrectomy and thrombectomy without mobilizing the liver and artificial vascular replacement of the IVC (Figure 3A). Histological findings revealed expanded necrosis and infiltration of foamy histiocytes with no viable cells in the surgical specimen, including in the thrombus (Figure 3B and C). Moreover, we investigated the expression levels of CD4, CD8, and CD20 in biopsy and surgical specimens by immunohistochemical examination (Figure 4). CD4⁺ and CD8⁺ cells were sparsely found in the biopsy specimens but were remarkably increased in the surgical specimens. In contrast, even though CD20⁺ cells were not found in the biopsy specimen, they were observed surrounded by CD4⁺ cells in the surgical specimen, which suggested that the formation of tertiary lymphoid structures (TLS) was recognized in the surgical specimens.

The perioperative course was uneventful, and the patient was discharged 10 days after surgery. No local recurrence or metastasis was observed 3 months after the discontinuation of nivolumab plus cabozantinib therapy.

**Discussion**

The efficacy of nivolumab plus cabozantinib was demonstrated in the CheckMate 9ER trial for metastatic RCC (7), with an objective response rate of 55.7%, CR rate of 8%, and progression disease (PD) rate of 5.6%. In addition, the health-related quality of life was significantly better with nivolumab plus cabozantinib compared to sunitinib at nearly all time points during treatment (7). Furthermore, the combination of nivolumab and cabozantinib showed promising efficacy in the treatment of patients with papillary, unclassified, and translocation-associated histological type metastatic non-clear cell RCC in a phase 2 study (8). In the present case report, a definitive diagnosis could not be made by biopsy, but the possibility of non-clear RCC was suggested. In addition, the tumor grew rapidly and its progression required immediate control. Therefore, we selected a combination of ICI plus TKI therapy with nivolumab plus cabozantinib.

There have been several reports on achieving pCR with ICI combination therapy for RCC with IVC thrombus, such as ipilimumab plus nivolumab (9-11), pembrolizumab plus axitinib (12), and avelumab plus axitinib (13). To our knowledge, this
is the first case in which a combination of nivolumab and cabozantinib as presurgical therapy resulted in pCR.

In a recent review article, Topalian et al. (14) reported the presence of tumor-specific CD8+ T cells and TLS in pretreatment specimens as factors associated with the efficacy of neoadjuvant ICI therapy. In particular, CD20+ B cells were associated with survival and immunotherapy response. The prognostic significance of tumor-infiltrating CD20+ B cells was generally concordant with that of CD3+ and/or CD8+ T cells, and the prognostic effect of T cells was generally stronger when tumor-infiltrating CD20+ B cells were also present (15-17). Our results suggested that nivolumab promotes the immune activity of CD20+ B cells by stimulating CD4+ T cells and forming TLS or directly blocking PD-1 expression on CD20+ B cells, and the increased CD20+ B cells contribute to nivolumab response together with CD8+ cells. We also previously reported a similar case of achieving pCR in a patient treated with presurgical pembrolizumab for chemoresistant upper urinary tract urothelial carcinoma (18). In contrast, cabozantinib has been shown to enhance anti-tumor T cell immunity by increasing T cell infiltration into the tumor bed. Furthermore, tumor antigens released from necrotic tumor tissue by cabozantinib may trigger increased tumor antigen presentation and recognition by CD8+ T cells, leading to enhanced immune response (19).

The limitation of this single case report is that a conclusion cannot be drawn on the response of RCC with IVC thrombus to nivolumab plus cabozantinib, based on a single patient. While the shrinkage of tumor thrombus allowed the patient to undergo less invasive surgery without any perioperative complications via ICI combination therapy, we must always keep in mind the risk of pulmonary embolism or the risk of disease progression (20). Furthermore, nivolumab plus cabozantinib could cause severe adverse events (AEs) caused by TKIs or immune related AEs, therefore careful monitoring until surgery is required (7). In addition, the histological subtype, such as clear cell or non-clear cell RCC, could not be confirmed in this patient because the surgical specimen showed no viable cells. Nevertheless, we believe that the information presented herein will contribute further insight into new therapeutic methods, including the neoadjuvant setting of combined immunotherapy, for RCC patients with IVC thrombus.
Figure 3. Gross examination showing the left kidney and tumor thrombus protruding from the left renal vein (yellow arrow) (A). Hematoxylin and eosin (H&E) staining showing extended necrosis and infiltration of foamy histiocytes without viable cells in the surgical specimen (B) (×100 magnification) and the tips of the tumor thrombus (C) (×40 magnification).

Figure 4. Hematoxylin and eosin (H&E) staining (×200 magnification) (A), CD4 (B), CD8 (C), and CD20 (D) staining of the biopsy specimen. H&E staining (×100 magnification) (E), CD4 (F), CD8 (G), CD20 (H) staining of the surgical specimen. CD20 was not found in the biopsy specimen but was present in the surgical specimen.
In conclusion, we showed that nephrectomy could be safely performed in an RCC patient with IVC thrombus after presurgical nivolumab plus cabozantinib therapy, resulting in pCR. CD20+ lymphocyte infiltration after nivolumab plus cabozantinib treatment suggests the efficacy of immunotherapy, as assessed via immunohistochemistry. Presurgical nivolumab plus cabozantinib therapy may be a curative treatment option for RCC with IVC thrombus in selected patients.
